Four-loop QCD β -function with different fermion representations of the gauge group

Zoller, M F

Abstract: We present analytical results at four-loop level for the β -function of the coupling of a generic gauge group and any number of different quark representations. From this we can directly derive the gluino contribution to the strong coupling β -function of supersymmetric extensions of the Standard Model.

1 Introduction

The Renormalization Group (RG) functions of non-Abelian gauge theories, especially the QCD β -function, are among the most precisely calculated objects in quantum field theory. The excellent agreement of theory predictions for the strong coupling at different scales with experimental results is among the great successes of particle physics, since the observed asymptotic freedom is the basis for theory predictions at hadron colliders.

An interesting special case in theoretical physics are conformal theories in which the β -functions vanish and the couplings are hence constant. The knowledge of the QCD β -function with an extended fermion sector is an important ingredient for the application of the sequential extended BLM approach [1–3], which aims at resumming the non-conformal parts of QCD observables into the scale of the coupling in a unique way, to extensions of the Standard Model (SM). A closely related approach is the Principle of Maximum Conformality and Commensurate Scale Relations developed in [4].

The β -function for the coupling $\alpha_s = \frac{g_s^2}{4\pi}$ is defined as

$$\beta(\alpha_s) = \mu^2 \frac{d\alpha_s}{d\mu^2} = \alpha_s \sum_{n=1}^{\infty} \left(\frac{\alpha_s}{4\pi} \right)^n \beta_{\alpha_s}^{(n)}. \quad (1.1)$$

and has been computed at one-loop [5, 6], two-loop [7–10], three-loop [11, 12] and four-loop [13, 14] level for a generic gauge group with one fermion representation.¹ Recently the five-loop result was published for QCD colour factors [27] and the terms $\propto n_f^3$ and $\propto n_f^4$ for a generic gauge group [28].

¹The RG functions of the full Standard Model are available at three-loop order for the gauge couplings [15–17], the Yukawa couplings [18, 19] and the parameters of the Higgs potential [18, 20–22]. The four-loop β -function for the strong coupling g_s was extended to include the dependence on the top-Yukawa coupling y_t and the Higgs self-coupling λ [23, 24]. The leading QCD induced four-loop contributions to the Higgs self-coupling β -function were presented in [25, 26].

In this paper we present the four-loop β -function for the coupling of a generic gauge group with an arbitrary number N_{rep} of fermion representations. One example is the extension of the QCD β -function to include not only n_f active quark flavours but also $n_{\tilde{g}}$ gluinos. At two-loop [29] and three-loop [30] level these results are available and are independently confirmed here. Recently, also the four-loop result for the gluino case was presented at a conference [31].

2 Details of the calculation

2.1 QCD with several fermion representations

The QCD Lagrangian is given by

$$\begin{aligned} \mathcal{L}_{QCD} = & -\frac{1}{4}G_{\mu\nu}^a G^{a\mu\nu} - \frac{1}{2(1-\xi)} (\partial_\mu A^{a\mu})^2 + \partial_\mu \bar{c}^a \partial^\mu c^a + g_s f^{abc} \partial_\mu \bar{c}^a A^{b\mu} c^c \\ & + \sum_q \left\{ \frac{i}{2} \bar{q} \overleftrightarrow{\not{D}} q + g_s \bar{q} \not{A} T^a q \right\}, \end{aligned} \quad (2.1)$$

with the gluon field strength tensor

$$G_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + g_s f^{abc} A_\mu^b A_\nu^c, \quad (2.2)$$

the structure constants f^{abc} of the gauge group, defined through

$$[T^a, T^b] = i f^{abc} T^c \quad (2.3)$$

with the group generators T^a , and q running over all quark flavours.

This can easily be generalized to include several fermion representations of the gauge group by substituting

$$\sum_q \left\{ \frac{i}{2} \bar{q} \overleftrightarrow{\not{D}} q + g_s \bar{q} \not{A} T^a q \right\} \rightarrow \sum_{r=1}^{N_{\text{rep}}} \sum_{q_r} \left\{ \frac{i}{2} \bar{q}_r \overleftrightarrow{\not{D}} q_r + g_s \bar{q}_r \not{A} T_r^a q_r \right\} \quad (2.4)$$

where r gives the representation and q_r runs over all fermion flavours/types of that representation.

For example in the strong sector of supersymmetric extensions of the Standard Model (SM) we find in addition to n_f quark flavours, which are Dirac fermions, $n_{\tilde{g}}$ gluinos, which are Majorana fermions. In the SM we have $n_{\tilde{g}} = 0$, in the MSSM $n_{\tilde{g}} = 1$.

This extended QCD Lagrangian is renormalized with the counterterm Lagrangian

$$\begin{aligned} \delta\mathcal{L}_{QCD} = & -\frac{1}{4}\delta Z_3^{(2g)} (\partial_\mu A_\nu^a - \partial_\nu A_\mu^a)^2 - \frac{1}{2}\delta Z_1^{(3g)} g_s f^{abc} (\partial_\mu A_\nu^a - \partial_\nu A_\mu^a) A_\mu^b A_\nu^c \\ & - \frac{1}{4}\delta Z_1^{(4g)} g_s^2 (f^{abc} A_\mu^b A_\nu^c)^2 + \delta Z_3^{(2c)} \partial_\mu \bar{c}^a \partial^\mu c^a + \delta Z_1^{(ccg)} g_s f^{abc} \partial_\mu \bar{c}^a A^{b\mu} c^c \end{aligned} \quad (2.5)$$

$$+ \sum_{r=1}^{N_{\text{rep}}} \sum_{q_r} \left\{ Z_2^{(q_r q_r)} \frac{i}{2} \bar{q}_r \overleftrightarrow{\not{D}} q_r + g_s Z_1^{(q_r q_r g)} \bar{q}_r \not{A} T_r^a q_r \right\} \quad (2.6)$$

The renormalization constant for the strong coupling can then be computed from

$$Z_{g_s} = \frac{Z_1^{(cgg)}}{Z_3^{(2c)} \sqrt{Z_3^{(2g)}}} \quad (2.7)$$

where we define the renormalization constants $Z = 1 + \delta Z$ in the $\overline{\text{MS}}$ -scheme. All divergent integrals are regularized in $D = 4 - 2\varepsilon$ space time dimensions.

2.2 Technicalities

All 1-particle-irreducible Feynman diagrams for the computation of $Z_3^{(2c)}$, $Z_3^{(2g)}$ and $Z_1^{(cgg)}$ are generated with QGRAF [32]. The C++ programs Q2E and EXP [33, 34] identify the topology of the diagram. The UV divergent part of the diagrams is calculated as described in detail in [35] introducing the same auxiliary mass parameter M^2 in every propagator denominator and cancelling subdivergencies $\propto M^2$ by introducing an unphysical gluon mass counterterm $\frac{M^2}{2} \delta Z_{M^2}^{(2g)} A_\mu^a A^{a\mu}$. This procedure was introduced in [36], further developed in [37] and also used e. g. in [13, 14, 18, 24, 26]. For a detailed explanation of this method see e. g. [35].

In the $\overline{\text{MS}}$ -scheme renormalization constants are independent of external momenta. Hence we Taylor expand to first order in the external momentum q for the ghost-gluon vertex² (which is $\propto q^\mu$) and to second order in the gluon self-energy ($\propto q^\mu q^\nu - q^2 g^{\mu\nu}$) as well as the ghost self-energy ($\propto q^2$). Then we use projectors on the integrals in order to make them scalar and q -independent, namely $\frac{q^\mu}{q^2}$ for the ghost-gluon vertex, $\frac{1}{q^2}$ for the ghost propagator and $\frac{q^\mu q^\nu}{q^4}$ as well as $\frac{q^{\mu\nu}}{q^2}$ for the gluon propagator. These expansions and projections as well as the fermion traces and counterterm insertions in lower order diagrams were done with FORM [38, 39]. The resulting tadpole integrals were computed with the FORM-based package MATAD [40] up to three-loop order. At four loops we use the C++ version of FIRE 5 [41, 42] in order to reduce the scalar integrals to Master Integrals which are available from [14]. For details on the reduction we refer to the previous paper [24].

The computation of the gauge group factors is based on the FORM package COLOR [43]. The implementation by the authors of [43] takes as input the colour diagrams expressed through the generators of the fermion representation $T_{ij}^a = \mathbf{T}(\mathbf{i}, \mathbf{j}, \mathbf{a})$ and the structure constants $f^{abc} = \mathbf{f}(\mathbf{a}, \mathbf{b}, \mathbf{c})$, i. e. the generators of the adjoint representation of the corresponding Lie algebra. The result is then given in terms of Casimir operators C_F and C_A of the fermion and adjoint representation, the trace T_F defined through

$$T_F \delta^{ab} = \mathbf{Tr} \left(T^a T^b \right) = T_{ij}^a T_{ji}^b \quad (2.8)$$

and higher order invariants built from symmetric tensors

$$d_R^{a_1 a_2 \dots a_n} = \frac{1}{n!} \sum_{\text{perm } \pi} \text{Tr} \left\{ T^{a_{\pi(1)}, R} T^{a_{\pi(2)}, R} \dots T^{a_{\pi(n)}, R} \right\}, \quad (2.9)$$

² q being the external momentum entering the ghost leg, the external momentum of the gluon is set to zero from the start. μ is the Lorentz index of the gluon.

where R marks the representation, in this case $T_{i,j}^{a,F} = T_{i,j}^a$ or $T_{bc}^{a,A} = f^{abc}$. The fermion representation has dimension d_F and the adjoint N_A . Each fermion loop is multiplied by the number of active fermion flavours n_f .

We extend this setup to take as input generators $T_{ij}^{a,1} = \mathbf{T1}(i,j,a)$, $T_{ij}^{a,2} = \mathbf{T2}(i,j,a)$, $T_{ij}^{a,3} = \mathbf{T3}(i,j,a)$, ... in order to account for different representations. The adjoint representation with the structure constants as generators is always present. The traces of these generators which are the objects simplified and reduced by COLOR also carry an index for the representation and all internal routines of the COLOR package as described in [43] are adapted to keep track of the fermion representation to which the produced invariants belong. We therefore have Casimir operators $C_{F,i}$ for the fermion representations ($i = 1, \dots, N_{\text{rep}}$) of dimensions $d_{F,i}$. The trace for each representation is given by $T_{F,i}$ defined as $T_{F,i}\delta^{ab} = \mathbf{Tr}(T^{a,i}T^{b,i})$ and the higher order invariants are constructed from symmetrized objects like

$$d_{F,i}^{abcd} = \frac{1}{6} \mathbf{Tr} \left(T^{a,i} T^{b,i} T^{c,i} T^{d,i} + T^{a,i} T^{b,i} T^{d,i} T^{c,i} + T^{a,i} T^{c,i} T^{b,i} T^{d,i} \right. \\ \left. + T^{a,i} T^{c,i} T^{d,i} T^{b,i} + T^{a,i} T^{d,i} T^{b,i} T^{c,i} + T^{a,i} T^{d,i} T^{c,i} T^{b,i} \right). \quad (2.10)$$

which are in turn built from the generators of the fermion representations. Analogously, d_A^{abcd} is constructed from the generators of the adjoint representation. A closed fermion loop is accompanied by a factor $n_{f,i}$ for the number of active fermion flavours of representation i .

Now, we could take a model with a fixed number of fermion representations, each given by its own field in QGRAF, and perform the calculation directly. But there is a more elegant way: We only use one field q in QGRAF for all fermion representations. Each fermion line then gets a different “representation” number $R = 1, 2, 3$ in our modified version of COLOR. However, this index R is just the number of the fermion line and does not correspond to one single representation of the gauge group, but in the end runs over all representations.

A diagram with one fermion line will then yield a result involving the trace **TF1** and the Casimirs **cF1** and **cA** as well as the dimensions **dF1** and **NA**. A diagram with two fermion lines results in **TF1**, **TF2**, **cA**, **dF1**, **dF2** and **NA**. In our four-loop calculation we encounter at most three fermion lines in the gauge boson and ghost self-energies and the ghost-gauge boson vertex correction. In the end we sum each index over all physical fermion representations because each fermion loop can be any fermion type. The advantage is obviously that we do not generate more diagrams than in pure QCD! In the same way that we sum over all quark types in massless QCD (using only one quark field in QGRAF and multiplying quark loops with n_f) we now sum over all fermion types, e. g. all quarks and all gluinos in the MSSM.

For the renormalization procedure, however, it is convenient to deal with explicit group factors. Since we can encounter at most three physical representations in one and the same

diagram we substitute, e. g. in a one-loop diagram

$$\mathbf{Nf*TF1} \rightarrow n_{f,1}T_{F,1} + n_{f,2}T_{F,2} + n_{f,3}T_{F,3}. \quad (2.11)$$

where the 1 on the lhs marks the number of the fermion line and the 1, 2, 3 on the rhs correspond to different representations of the gauge group.³ In this way we compute the gauge boson, ghost and fermion self-energy as well as the ghost-gauge boson and fermion-gauge boson vertex corrections at one-loop, two-loop and three-loop level in order to have the correct counterterms available. The explicit use of all fermion representations in the counterterms as well as in the diagrams in which they are inserted and the diagrams to which the lower-loop diagrams with counterterms are added is necessary in order to ensure that e. g. the one-loop counterterm $\delta Z_3^{(2g)}$ can be used in order to cancel the subdivergence stemming from the first as well as the one stemming from the second fermion loop in a higher-loop diagram.

After all lower-loop diagrams with counterterms are added to the diagrams of the loop order we want to compute we can simplify the notation again by substituting⁴, e. g.

$$n_{f,1}T_{F,1} \rightarrow \sum n_{f,i}T_{F,i} - n_{f,2}T_{F,2} - n_{f,3}T_{F,3}. \quad (2.12)$$

Note that the final result which only contains $n_{f,i}, T_{F,i}, C_{F,i}, d_{F,i}, \dots$ is not restricted to three representations, but is valid for any number N_{rep} .

3 Results

In this section we give the results for the four-loop β -function of the strong coupling g_s with an arbitrary number of fermion representations. The number of active fermion flavours of representation i is denoted by $n_{f,i}$.

$$\beta_{\alpha_s}^{(1)} = -\frac{11}{3}C_A + \sum_i \frac{4}{3}n_{f,i}T_{F,i} \quad (3.1)$$

$$\beta_{\alpha_s}^{(2)} = -\frac{34}{3}C_A^2 + \sum_i n_{f,i}T_{F,i} \left[4C_{F,i} + \frac{20}{3}C_A \right] \quad (3.2)$$

$$\begin{aligned} \beta_{\alpha_s}^{(3)} = & -\frac{2857}{54}C_A^3 + \sum_i n_{f,i}T_{F,i} \left[-2C_{F,i}^2 + \frac{205}{9}C_A C_{F,i} + \frac{1415}{27}C_A^2 \right] \\ & - \sum_{i,j} n_{f,i}n_{f,j}T_{F,i}T_{F,j} \left[\frac{44}{9}C_{F,i} + \frac{158}{27}C_A \right] \end{aligned} \quad (3.3)$$

$$\beta_{\alpha_s}^{(4)} = - \left(\frac{150653}{486} - \frac{44}{9}\zeta_3 \right) C_A^4 + \left(\frac{80}{9} - \frac{704}{3}\zeta_3 \right) \frac{d_A^{abcd}d_A^{abcd}}{N_A}$$

³The substitution rules can become quite involved in higher order diagrams. It is therefore convenient to collect all combinations $\mathbf{Nf}^{x_1}*\mathbf{TF1}^{x_2}*\mathbf{CF1}^{x_3}*\mathbf{TF2}^{x_4}*\mathbf{CF2}^{x_5}*\mathbf{TF3}^{x_6}*\mathbf{CF3}^{x_7}$ in a function $\mathbf{C}(\mathbf{x1}, \dots, \mathbf{x7})$. The factors $\mathbf{C}(\mathbf{x1}, \dots, \mathbf{x7})$ are then substituted by the proper symmetrization over three representations.

⁴Again it is useful to collect $n_{f,1}^{x_1}n_{f,2}^{x_2}n_{f,3}^{x_3}T_{F,1}^{x_4}T_{F,2}^{x_5}T_{F,3}^{x_6}C_{F,1}^{x_7}C_{F,2}^{x_8}C_{F,3}^{x_9}$ in a function $\mathbf{CR}(\mathbf{x1}, \dots, \mathbf{x9})$ for which then the substitution rules are formulated. This also provides a check that all terms have indeed been absorbed into the compact notation when no $\mathbf{CR}(\dots)$ survives in the end.

$$\begin{aligned}
& + \sum_i n_{f,i} T_{F,i} \left[-46 C_{F,i}^3 + \left(\frac{4204}{27} - \frac{352}{9} \zeta_3 \right) C_A C_{F,i}^2 - \left(\frac{7073}{243} - \frac{656}{9} \zeta_3 \right) C_A^2 C_{F,i} \right. \\
& \quad \left. + \left(\frac{39143}{81} - \frac{136}{3} \zeta_3 \right) C_A^3 \right] - \sum_i n_{f,i} \left(\frac{512}{9} - \frac{1664}{3} \zeta_3 \right) \frac{d_{F,i}^{abcd} d_A^{abcd}}{N_A} \\
& + \sum_{i,j} n_{f,i} n_{f,j} T_{F,i} T_{F,j} \left[- \left(\frac{184}{3} - 64 \zeta_3 \right) C_{F,i} C_{F,j} + \left(\frac{304}{27} + \frac{128}{9} \zeta_3 \right) C_{F,i}^2 \right. \\
& \quad \left. - \left(\frac{17152}{243} C_A C_{F,i} + \frac{448}{9} \zeta_3 \right) C_A C_{F,i} - \left(\frac{7930}{81} + \frac{224}{9} \zeta_3 \right) C_A^2 \right] \\
& + \sum_{i,j} n_{f,i} n_{f,j} \left(\frac{704}{9} - \frac{512}{3} \zeta_3 \right) \frac{d_{F,i}^{abcd} d_{F,j}^{abcd}}{N_A} \\
& - \sum_{i,j,k} n_{f,i} n_{f,j} n_{f,k} T_{F,i} T_{F,j} T_{F,k} \left[\frac{1232}{243} C_{F,i} + \frac{424}{243} C_A \right].
\end{aligned} \tag{3.4}$$

The pure QCD part of (3.4) agrees with [13, 14].

The special case of QCD plus additional gluinos is derived by choosing $N_{rep} = 2$ and

$$\begin{aligned}
n_{f,1} &= n_f, & n_{f,2} &= \frac{n_{\tilde{g}}}{2}, \\
T_{F,1} &= T_F, & T_{F,2} &= C_A, \\
C_{F,1} &= C_F, & C_{F,2} &= C_A,
\end{aligned} \tag{3.5}$$

where the factor $\frac{1}{2}$ in $n_{f,2} = \frac{n_{\tilde{g}}}{2}$ is due to the Majorana nature of the gluinos (see e. g. [30]).

We find

$$\beta_{\alpha_s}^{(1)} = -\frac{11}{3} C_A + \frac{2}{3} n_{\tilde{g}} C_A + \frac{4}{3} n_f T_F \tag{3.6}$$

$$\beta_{\alpha_s}^{(2)} = -\frac{34}{3} C_A^2 + \frac{16}{3} n_{\tilde{g}} C_A^2 + n_f T_F \left[4 C_F + \frac{20}{3} C_A \right] \tag{3.7}$$

$$\begin{aligned}
\beta_{\alpha_s}^{(3)} &= -\frac{2857}{54} C_A^3 + \frac{988}{27} n_{\tilde{g}} C_A^3 - \frac{145}{54} n_{\tilde{g}}^2 C_A^3 + n_f T_F \left[-2 C_F^2 + \frac{205}{9} C_A C_F + \frac{1415}{27} C_A^2 \right] \\
& - n_f^2 T_F^2 \left[\frac{44}{9} C_F + \frac{158}{27} C_A \right] - n_{\tilde{g}} n_f C_A T_F \left[\frac{22}{9} C_F + \frac{224}{27} C_A \right]
\end{aligned} \tag{3.8}$$

$$\begin{aligned}
\beta_{\alpha_s}^{(4)} &= - \left(\frac{150653}{486} - \frac{44}{9} \zeta_3 \right) C_A^4 + \left(\frac{80}{9} - \frac{704}{3} \zeta_3 \right) \frac{d_A^{abcd} d_A^{abcd}}{N_A} \\
& + n_{\tilde{g}} \left[\left(\frac{68507}{243} - \frac{52}{9} \zeta_3 \right) C_A^4 - \left(\frac{256}{9} - \frac{832}{3} \zeta_3 \right) \frac{d_A^{abcd} d_A^{abcd}}{N_A} \right] \\
& - n_{\tilde{g}}^2 \left[\left(\frac{26555}{486} - \frac{8}{9} \zeta_3 \right) C_A^4 + \left(\frac{176}{9} - \frac{128}{3} \zeta_3 \right) \frac{d_A^{abcd} d_A^{abcd}}{N_A} \right] - \frac{23}{27} n_{\tilde{g}}^3 C_A^4 \\
& + n_f T_F \left[-46 C_F^3 + \left(\frac{4204}{27} - \frac{352}{9} \zeta_3 \right) C_A C_F^2 - \left(\frac{7073}{243} - \frac{656}{9} \zeta_3 \right) C_A^2 C_F \right. \\
& \quad \left. + \left(\frac{39143}{81} - \frac{136}{3} \zeta_3 \right) C_A^3 \right] - n_f \left(\frac{512}{9} - \frac{1664}{3} \zeta_3 \right) \frac{d_F^{abcd} d_A^{abcd}}{N_A} \\
& + n_f^2 T_F^2 \left[- \left(\frac{1352}{27} - \frac{704}{9} \zeta_3 \right) C_F^2 - \left(\frac{17152}{243} + \frac{448}{9} \zeta_3 \right) C_A C_F \right. \\
& \quad \left. - \left(\frac{7930}{81} + \frac{224}{9} \zeta_3 \right) C_A^2 \right] + n_f^2 \left(\frac{704}{9} - \frac{512}{3} \zeta_3 \right) \frac{d_F^{abcd} d_F^{abcd}}{N_A}
\end{aligned}$$

$$\begin{aligned}
& -n_f^3 T_F^3 \left[\frac{1232}{243} C_F + \frac{424}{243} C_A \right] \\
& + n_{\tilde{g}} n_f C_A T_F \left[\left(\frac{152}{27} + \frac{64}{9} \zeta_3 \right) C_F^2 - \left(\frac{23480}{243} - \frac{352}{9} \zeta_3 \right) C_A C_F \right. \\
& \left. - \left(\frac{30998}{243} + \frac{128}{3} \zeta_3 \right) C_A^2 \right] + n_f n_{\tilde{g}} \left(\frac{704}{9} - \frac{512}{3} \zeta_3 \right) \frac{d_F^{abcd} d_A^{abcd}}{N_A} \\
& - n_{\tilde{g}}^2 n_f C_A^2 T_F \left[\frac{308}{243} C_F + \frac{934}{243} C_A \right] - n_{\tilde{g}} n_f^2 C_A T_F^2 \left[\frac{1232}{243} C_F + \frac{1252}{243} C_A \right],
\end{aligned} \tag{3.9}$$

in agreement with [31].

4 Conclusions

We have presented an analytical result for the four-loop β -function of the strong coupling g_s in a QCD-like model with arbitrarily many fermion representations. As an application we have given the result for the four-loop β -function of QCD plus gluinos.
